

The question of the thread oriented submission becomes an issue.

Also, the feeding of data structures becomes an issue for the parent application:

- The manner the sub-tasks are divided up as a list of files (input). Items copied into these directories into these directories are the data (photos) and the programs to work on them.
- These structures include message forwarding which is the purpose of a NeXTStep delegate.
- “A delegate is an object directed to carry out an action by another object.” page 456 [?]
- Once the sub-tasks and its data are determined, the sub job is copied out of the bundle (app), and the executable (script), then the sub-task queue is loaded.
- The rest of the methods are delegate methods.
